## **A Massively Parallel Assay for Understanding Receptor-Ligand Relationships**

Eric Jones  
2018 In this dissertation, I describe the development and application of a multiplexed method for high-throughput screening of receptor-ligand interactions. Such interactions underpin our cells' ability to sense and

respond to their environment and represent a primary venue for therapeutic intervention. By leveraging advancements in DNA synthesis, genome editing, and next-generation sequencing, we have built a platform to measure the activity of a mixed population of receptors through RNA-seq of barcoded genetic reporters. We demonstrate the utility

of the method for large-scale identification of chemical-receptor interactions and biochemical characterization of receptor function. First, small molecules can interact with many biological targets in an organism, and uncovering these relationships is critical for modulating their function. Mammalian olfactory receptors (ORs), a large family of G protein-coupled receptors (GPCRs), mediate the sense of smell through activation by odorant small molecules. Each OR can respond to many odorants, and vice versa, making exploring this space one interaction at a time difficult. We used the platform to screen chemicals against a multiplexed library of ORs. We screened three concentrations of 181 odorants, where in each well we record the activity of 39 ORs simultaneously, and identified 79 novel

associations, including ligands for 15 orphan receptors. Second, GPCRs are ubiquitous throughout mammalian biology. They are conformationally dynamic which is essential to their function, but makes them recalcitrant to many techniques of structural determination. Here, we mutagenize and characterize all 7,828 possible missense variants of the beta-2-adrenergic receptor. On a broad scale, we find positions that respond similarly to mutation share certain properties of their environment and functional role within the protein. We recapitulate the importance of known critical residues and motifs and identify new residues important for function. Additionally, we describe an unreported, conserved extracellular motif maintained in both the inactive and active conformation of the protein that is essential for function. As a whole,

multiplexed screening enables the investigation of many outstanding questions in receptor biology. It is applicable to the disparate biological niches and systems that receptors occupy. As demonstrated in this dissertation, it has the potential to be a powerful tool for mapping receptor-ligand interactions and understanding receptor biochemistry.

Langley first proposed the role of "receptive substances" as the site of drug action from his observations on the effects of nicotine and curare at the myoneural junction. The many advances in our understanding of receptor biology that have occurred during the intervening period mirror the extraordinary growth of knowledge in the biological sciences and in cell and molecular biology in particular. Receptor biology, in common with many other topics in contemporary biology, is on the threshold of a transition from being a descriptive, phenomenological discipline to one in which underlying mechanisms and regulatory principles can be defined with increasing precision. This change, together with the evolution of powerful analytical techniques and timely convergence of ideas from a number of previously separate fields of inquiry, is generating an increasingly

unified theoretical and experimental framework for the study of receptor function. These themes, and the mood of anticipation that a real understanding of receptor function in health and disease is emerging, are reflected in in this volume, which summarizes the proceedings of the Second papers on Smith Kline & French Research Symposium on New Horizons in Therapeutics held in Philadelphia in 1984.

### **The Biology of Nicotine Dependence**

Gregory R. Bock 2008-04-30 Nicotine is considered to be the main agent in the maintenance of the tobacco smoking habit and is largely responsible for the behavioral and physiological responses to the inhalation of tobacco smoke. This work presents advances made in the elucidation of the action of nicotine in the body-- essential information for developing treatments to help people give up

smoking. The book reviews the progress made in identifying nicotinic acetylcholine receptors in the brain, using the techniques of molecular biology to characterize receptors and investigate the functional differences between receptors composed of different types of subunits. Sex-specific differences in the response to nicotine, the effects of nicotine on locomotor activity, and its still-debated influence on cognitive performance are considered. The book also examines the habit-forming role of nicotine, the development of tolerance to nicotine, and the less clearly understood phenomenon of withdrawal. Also discusses some potential therapeutic strategies.

**A3 Adenosine Receptors from Cell Biology to Pharmacology and Therapeutics** Pier Andrea

Borea 2009-12-01 This book, with its 16 chapters, documents the present state of knowledge of the adenosine A receptor. It covers a wide range of information, including data from 3 studies of theoretical, molecular and cellular pharmacology, signal transduction, integrative physiology, new drug discoveries and clinical applications. It fills an important gap in the literature since no alternative source of such information is currently available. Although the A receptor is increasingly being recognized for 3 its increasing number of biological roles throughout the body and many A receptor 3 ligands have proven useful in elucidating peripheral and central pathologies, many issues remain unresolved. Moreover, research activity in this field continues to grow exponentially, resulting in a constant flow of new information. The

chapters in this book cover both basic science and the relevant applications and provide an authoritative account of the current status of the field. They have enabled my goal as editor to make "A Adenosine Receptors from Cell Biology to Pharmacology and 3 Therapeutics" an up to date, scientifically excellent, reference source, attractive to basic and clinical scientists alike, a reality. Detailed understanding of the physico-chemical aspects and molecular biology of the A receptor provides a solid basis for its future development as a target for 3 adenosine-based pharmacotherapies (Chapters 2 and 3).

### *Immunobiology of Natural Killer Cell Receptors* Eric Vivier 2005-12-20

Natural Killer (NK) cells are large granular lymphocytes of the innate immune system. They are widespread throughout the body, being present in both lymphoid organs and non-lymphoid peripheral tissues. NK cells are involved in direct innate immune reactions against viruses, bacteria, parasites and other triggers of pathology, such as malignant transformation, all of which cause stress in affected cells. Importantly, NK cells also link the innate and adaptive immune responses, contributing to the initiation of adaptive immune responses and executing adaptive responses using the CD16 FcγRIIIA immunoglobulin Fc receptor. Such responses

are mediated through two major effector functions, the direct cytotoxicity of target cells and the production of cytokines and chemokines. The authors focus here on the nature of recognition events by NK cells and address how these events are integrated to trigger these distinct and graded effector functions.

### **Molecular Biology of Steroid and Nuclear Hormone Receptors**

Leonard Freedman  
2012-12-06 Intracellular Receptors: New Instruments for a Symphony of Signals In the late eighteenth century, it was proposed on theoretical grounds that each of the body's organs, beginning with the brain, must be "a factory and laboratory of a specific humor which it returns to the blood", and

that these circulating signals "are indispensable for the life of the whole" (Bordeu 1775). During the nineteenth century, some remarkable physiological experiments revealed the actions of humoral factors that affected the form and function of multiple tissues, organs and organ systems within the body (Berthold 1849); much later, the chemical and molecular nature of some of those factors was determined. Against this deep historical backdrop of the founding studies of intercellular signaling, molecular biology sprang into existence a mere forty years ago, rooted in the revelation of regulable gene expression in bacteria. But contemporaneous with those classical analyses of transcriptional regulation of the lactose operon, the modern era of signal transduction was inaugurated by the identification of cAMP as a second messenger -- an

intracellular mediator of hormonal activation of glycogen catabolism (Sutherland and Rall 1960). Later in that same decade, it emerged that cAMP is a critical signal not only in metazoans, but even in bacteria, where it serves an analogous function as a critical switch that activates expression of genes required for catabolism of complex carbon sources, including those of the lactose operon.

*Nuclear Receptors* Chris M. Bunce 2010-03-11 In 1890 a case of myxedema was treated in Lisbon by the implantation of a sheep thyroid gland with the immediate improvement in the patient's condition. A few years later, medications for the then ill-explained condition of the menopause included tablets made from cow ovaries. In the first quarter of the 20th century the identification of vitamin D, and its sunlight driven production in skin, paved the way to the elimination

of rickets as a major medical problem. Twenty years or so later, Sir Vincent Wigglesworth established the endocrine basis of developmental moulting in insects, arguably the most commonly performed animal behaviour on Planet Earth. A paradigm that would unify these disparate observations arose between 1985 and 1987 beginning with the identification of the glucocorticoid receptor and the nuclear receptor superfamily. What follows is a timely and positive manifestation of the capacity, productivity and value of international human scientific endeavour. Based on intrigue, lively competition and cooperation a global effort has rapidly fostered a school of biology with widespread ramifications for the understanding of metazoan animals, the human condition and the state of the planet. **Fc Receptors** Marc Daeron 2014-08-12 This volume provides a state-of-the-art update on Fc Receptors (FcRs). It is divided into five parts. Part I, Old and New FcRs, deals with the long-sought-after Fc $\mu$ R and the recently discovered FCRL family and TRIM21. Part II, FcR Signaling, presents a computational model of Fc $\epsilon$ RI signaling, novel calcium channels, and the lipid phosphatase SHIP1. Part III, FcR Biology, addresses major physiological functions of FcRs, their glycosylation, how they induce and regulate both adaptive immune responses and inflammation, especially in vivo, FcR humanized mice, and the multifaceted properties of FcRn. Part IV, FcRs and Disease, discusses FcR polymorphism, FcRs in

rheumatoid arthritis and whether their FcRs make macaques good models for studying HIV infection. In Part V, FcRs and Therapeutic Antibodies, the roles of various FcRs, including Fc $\gamma$ RIIB and Fc $\alpha$ RI, in the immunotherapy of cancer and autoimmune diseases using monoclonal antibodies and IVIg are highlighted. All 18 chapters were written by respected experts in their fields, offering an invaluable reference source for scientists and clinicians interested in FcRs and how to better master antibodies for therapeutic purposes. Proceedings of the International Symposium on Quantum Biology and Quantum Pharmacology Per-Olov Löwdin 1978 *Receptors* Douglas A. Lauffenburger 1996-01-11 *Receptors: Models for Binding, Trafficking, and Signaling* bridges the gap between chemical engineering and cell biology by lucidly and practically

demonstrating how a mathematical modeling approach combined with quantitative experiments can provide enhanced understanding of cell phenomena involving receptor/ligand interactions. In stressing the need for a quantitative understanding of how receptor-mediated cell functions depend on receptor and ligand properties, the book offers comprehensive treatments of both basic and state-of-the-art model frameworks that span the entire spectrum of receptor processes--from fundamental cell surface binding, intracellular trafficking, and signal transduction events to the cell behavioral functions they govern, including proliferation, adhesion, and migration. The book emphasizes mechanistic models that are accessible to experimental testing and includes detailed examples of important contemporary issues. This much-needed

book introduces chemical engineers and bioengineers to important problems in receptor biology and familiarizes cell biologists with the insights that can be gained from engineering analysis and synthesis. As such, chemical engineers, researchers, and advanced students in the fields of biotechnology, biomedical sciences, bioengineering, and molecular cell biology will find this book to be conceptually rich, timely, and useful.

Mineralocorticoid Receptor*

Brian Harvey 2019-09-25

This book is an open access dissemination of the EU COST Action ADMIRE in Aldosterone/Mineralocorticoid Receptor (MR) physiology and pathophysiology.

Aldosterone is the major hormone regulating blood pressure. Alterations in blood levels of aldosterone and genetic mutations in the MR receptor are major causes of hypertension and comorbidities. Many of the drugs in clinical use, and in development for treating hypertension, target aldosterone and MR actions in the kidney and cardiovascular system. The ADMIRE book assembles review chapters from 16 European ADMIRE laboratories providing the latest insights into mechanisms of aldosterone synthesis/secretion, aldosterone/MR physiology and signaling, and the pathophysiological roles of

aldosterone/MR activation.

2012-12-06 LESLIE L.

IVERSEN The present series of volumes is well timed, as the impact of molecular genetics on pharmacology has been profound, and a comprehensive review of the rapid advances of the past decade is much needed. Since the pioneering work of Dale, Ariens, and others in the early years of this century, much of pharmacology has been founded on the concept of receptors. To begin with, the receptor was conceived of as a "black box," which recognized and transduced the biological effects of neurotransmitters, hormones, or other biological messengers-and which could also represent a target for man-made drugs. It is only in the last two decades that "molecular

pharmacology" has blossomed, first with the advent of radioligand binding techniques and second messenger studies which greatly facilitated the biochemical study of drug-receptor interactions, and latterly with increasing knowledge of the molecular architecture of the receptor proteins themselves. This started with the traditional biochemical approach of isolating and purifying the receptor molecules. This proved to be a task of immense technical difficulty because of the low density of receptors in most biological source tissues, although there were some notable successes, e. g. , the purification of the nicotinic acetylcholine receptor from the electric organ of Torpedo. It was the application of molecular genetics technology during the 1980s, however, which really accelerated progress in this field.

## **and Clinical Implications**

Naranjan S. Dhalla

2012-12-06 The relationship between angiotensin II and hypertension was established in 1898 when angiotensin II was shown to modulate systemic blood pressure. Over the intervening decades, a complete characterization of the renin-angiotensin system (RAS) has been achieved, and our understanding of its biochemistry and physiology has led to the directed development of agents such as ACE inhibitors and receptor antagonists capable of controlling hypertension. More recently, it was shown that angiotensin II is secreted within certain tissues and that these tissue-specific systems operate independently of the systemic RAS. The novel concept that angiotensin II regulates a number of cardiovascular processes that are unrelated to blood pressure has renewed the

interest of both basic and clinical scientists in angiotensin II. The association between angiotensin II and cardiac growth, in particular, has indicated that therapies currently in use for hypertension may have direct application to the treatment of heart failure. The Manitoba Cardiovascular Forum on Angiotensin Receptor Blockade in Winnipeg was convened October 18-20, 1996 to examine the clinical and basic aspects of angiotensin receptor biology as they apply to hypertension and heart failure. In addition, the potential treatment of these conditions using specific angiotensin receptor antagonists was addressed within the context of their immediate therapeutic application and future potential.

A. Azzi  
2012-12-06 This manual follows at a distance of 3 years the previous one entitled *Membrane Proteins*, and, like its predecessor, it is the result of an International Advanced Course sponsored by FEBS, SKMB and SNG, which was held in Bern in September 1983. The experiments offered to the students in the course had to be largely up-dated or chosen from new areas of membrane research, because of the substantial and rapid development of the field. Using the protocols of the course, the participants (graduate students, postdoctoral fellows and also senior

scientists), in most cases not at all expert in biomembrane research, were able to repeat all the experiments successfully. Those few protocols which for some reason did not fulfill the role we expected were modified. These protocols have now been collected in this manual, which we are able to offer to a number of biology, biochemistry and biophysics laboratories, hoping that the selected number of methods which have been successfully used during the Advanced Course may be useful to them. This manual is also intended for teachers of practical classes, who may use it as a text book and as source of selected references, collected not in the library, but in the laboratory, from the notebooks of the young researchers who have contributed so much to the success of the Course.

Josef T. Kittler 2006-03-27  
Exploring the diverse tools and technologies used to study synaptic processes, *The Dynamic Synapse: Molecular Methods in Ionotropic Receptor Biology* delineates techniques, methods, and conceptual advances for studying neurotransmitter receptors and other synaptic proteins. It describes a broad range of molecular, biochemical, imaging, and

electrophysiological approaches for studying the biology of synapses. Specific topics include the use of proteomics to study synaptic protein complexes, the development of phosphorylation state specific antibodies, post-genomic tools applied to the study of synapses and RNA interference in neurons. In addition, several chapters focus on methods for gene and protein delivery into neuronal tissue. The use of biochemical, electrophysiological and optical tagging techniques to study the movement and membrane trafficking of neurotransmitter receptors in the membrane of live nerve cells are also discussed. To complement these approaches, the application of approaches for achieving long-term alterations in the genetic complement of neurons in vivo using viral vectors or homologous recombination of ES cells are also described.

## **Neuromorphic Olfaction**

Krishna C. Persaud

2016-04-19 Many advances have been made in the last decade in the understanding of the computational principles underlying olfactory system functioning. Neuromorphic Olfaction is a collaboration among European researchers who, through NEUROCHEM (Fp7-Grant Agreement Number 216916)—a challenging and innovative European-funded project—introduce novel computing paradigms and biomimetic artifacts for chemical sensing. The implications of these findings are relevant to a wide audience, including researchers in artificial olfaction, neuroscientists, physiologists, and scientists working with chemical sensors. Developing neuromorphic olfaction from conceptual points of view to practical applications, this cross-disciplinary book examines: The biological components

of vertebrate and invertebrate chemical sensing systems The early coding pathways in the biological olfactory system, showing how nonspecific receptor populations may have significant advantages in encoding odor intensity as well as odor identity The redundancy and the massive convergence of the olfactory receptor neurons to the olfactory bulb A neuromorphic approach to artificial olfaction in robots Reactive and cognitive search strategies for olfactory robots The implementation of a computational model of the mammalian olfactory system The book's primary focus is on translating aspects of olfaction into computationally practical algorithms. These algorithms can help us understand the underlying behavior of the chemical senses in biological systems. They can also be translated into practical applications, such as robotic

navigation and systems for uniquely detecting chemical species in a complex background.

factors are hormone-related substances produced by many tissues and play an important role in controlling growth and development. While the exact physiological roles of growth factors have yet to be elucidated, they play important roles in the regulation of cellular proliferation and/or differentiation during ontogenesis, growth and differentiation. During recent years there has been a substantial increase in research related to peptide growth factors, their receptors, and modes of action. With the discovery and characterization of numerous growth factors, it became clear that these growth factors had multiple features in common with classic hormones as well as with oncogenes. Furthermore, there are distinct families of growth factors based either on structural or functional similarities.

## **Allosteric Modulation of G Protein-Coupled**

**Receptors** Robert Laprairie

2022-02-18 Allosteric Modulation of G Protein-Coupled Receptors reviews fundamental information on G protein-coupled receptors (GPCRs) and allosteric modulation, presenting original research in the area and collectively providing a comprehensive description of key issues in GPCR allosteric modulation. The book provides background on core concepts of molecular pharmacology while also introducing the most important advances and studies in the area. It also discusses key methodologies. This is an essential book for researchers and advanced students engaged in pharmacology, toxicology and pharmaceutical sciences training and research. Many of the GPCR-targeted drugs

released in the past decade have specifically worked via allosteric mechanisms.

Unlike direct orthosteric-acting compounds that occupy a similar receptor site to that of endogenous ligands, allosteric modulators alter GPCR-dependent signaling at a site apart from the endogenous ligand. Recent methodological and analytical advances have greatly improved our ability to understand the signaling mechanisms of GPCRs. We now know that allostery is a common regulatory mechanism for all GPCRs and not – as we once believed – unique to a few receptor subfamilies.

Introduces background on core concepts of molecular pharmacology, including statistical analyses, non-linear regression, complex models and GPCR-dependent signal transduction as they relate to allosteric modulation  
Discusses critical advances and landmark studies,

including discoveries in the area of GPCR allosteric modulation, which are reviewed for their importance in positive and negative regulation, protein-protein interactions, and small molecule drug discovery. Includes key methodologies used to study allosteric modulation at the in silico, in vitro, and in vivo levels of drug discovery and characterization.

#### The Serotonin Receptors

Bryan L. Roth 2008-08-17 A comprehensive, state-of-the-art review of our current understanding of the molecular and structural biology of 5-HT receptors and their potential use for drug discovery. The authors describe the anatomical, cellular, and subcellular distribution of 5-HT receptors and demonstrate a powerful approach to elucidating their physiological role using knockout mice in which the 5-HT receptors were deleted. They also review our understanding of the

physiological role(s) of 5-HT receptors based mainly on studies performed in genetically engineered mice. Highlights include discussions of the behavioral phenotypes of 5-HT receptor knockout animals, the molecular biology and pharmacology of 5-HT receptors, and insights into the complexity of 5-HT receptor signal transduction.

Gage 2019-04-01 This book covers a wide range of state-of-the-art methodologies and detailed protocols currently used to study the actions that lipid-activated nuclear receptors and their co-regulators have in tissues and immune cell types considered classic metabolic “powerhouses”. This includes the liver,

adipose tissue, and monocytes/macrophages present in these and other metabolic tissues. While the main focus is on the oxysterol receptor or Liver X Receptor (LXR), the majority of the methods described can be easily applied to multiple nuclear receptors, as well as to other tissues or cell types. Written in the highly successful Methods in Molecular Biology series format, chapters include

introductions to their respective topics, lists of the necessary materials and reagents, step-by-step, readily reproducible laboratory protocols, and tips on troubleshooting and avoiding known pitfalls. Authoritative and cutting-edge, *Lipid-Activated Nuclear Receptors: Methods and Protocols* serves as an ideal guide for researchers pursuing the vital study of nuclear receptor biology and beyond.
